

1998: This site is less than 10 miles from the Atlantic. In the churchyard is found this pair of windswept female yews.

Tree 1, south of the church, is an outpouring of branches close to the ground. Some lay across each other and appear fused together. Others spread along the ground and at a distance of up to 10' from the bole some have taken root, while others have become partly buried and emerge several feet further on in a new burst of growth.

Tree 2, southwest of the church, takes the full force of the westerly wind, so foliage on its western side was thin, and much of it brown. It was however healthier on the remainder of the tree. Low growing branches made walking beneath hazardous. There were few arils to be seen on this yew at a time in the year when the female tree is usually easy to identify.
