1998: Two male yews grow at this site. The largest is SE of the church and consists of two fragments separated by a large gap. The larger fragment is semi-circular joined by 2 smaller pieces at heights of 2' and 5'. There had been severe fire damage and the tree was also competing with elder, which grew against the bole and filled some of the hollow spaces. Girth was approximately 30' at 4'.

In 2013, when the photographs were taken, it appeared in excellent health, apart from a single dead branch. Girth around the main fragment between the ground and 1' was above 20'. Around the smaller fragment it was above 10' at 1', and around both fragments was above 28'.

The smaller girthed yew is the most easterly of the pair. From the church side the tree could not be approached through thick elder growing up to 20' in height close to the tree. The yew grows on a considerable mound and from below could be seen its well established internal growth. A dead section has separated from the tree and another will soon decay to lessen further the present girth of 15' 4" at 1'.
