

2016: A large hollow male yew, covered in rich green foliage, grows close to the church porch on the south side of the church, number 1 on the plan. The hollow is unusually not on the side facing the church. The space is large enough to stand inside and a few branch holes let in the daylight. The gash can be followed to a height of about 20'. I recorded a girth of 16' 4" at 2' above the ground, where a root bulges towards the church. Two years earlier in 2014 Peter Norton recorded a girth of 16' 4" at about 18" (natural waistline).

Yew 2, above right, is young and consists of 3 upright stems from close to the ground.

Yew 3 is male and grows towards the western end of the churchyard, about 50m from the tower. It consists of many upright stems on an elongated bole with a girth of about 9'.
